

Oral Submucous Fibrosis: Review on Etiopathogenesis

Sunita N Dyavanagoudar*

Department of Oral Pathology, Sri Hassanamba Dental College and Hospital, Vidyanagar, Hassan, Karnataka, India

Abstract

Summary data from recent epidemiological studies provide overwhelming evidence that areca nut is the main aetiological factor for OSF. Commercially freeze dried products such as pan masala, Guthka and mawa have high concentrates of areca nut per chew and appear to cause OSF more rapidly than by self prepared conventional betel quid that contain smaller amounts of areca nut. It is logical to hypothesize that the increased collagen synthesis or reduced collagen degradation as possible mechanisms in the development of the disease. These chemicals appear to interfere with the molecular processes of deposition and/or degradation of extracellular matrix molecules such as collagen. In vitro studies on human fibroblasts using areca extracts or chemically purified arecoline support the theory of fibroblastic proliferation and increased collagen formation that is also demonstrable histologically in human OSF tissues. The copper content of areca nut is high and the possible role of copper as a mediator of fibrosis is supported by the demonstration of up regulation of lysyl oxidase in OSF biopsies. It has been postulated that areca nut may also induce the development of the disease by increased levels of cytokines in the lamina propria. Current evidence implicates collagen-related genes in the susceptibility and pathogenesis of OSF. The individual mechanisms operating at various stages of the disease—initial, intermediate and advanced—need further study in order to propose appropriate therapeutic interventions.

Keywords: Oral Submucous fibrosis (OSF); Arecanut; Arecoline; Arecadine; TGF β ; Basis fibroblastic growth factor

Introduction

Oral submucous fibrosis (OSF) is a high risk precancerous condition which was first described in the early 1950s characterized by changes in the connective tissue fibers of the lamina propria and deeper parts leading to stiffness of the mucosa and restricted mouth opening seen predominantly in people of Asian descent. The disease is predominantly seen in India, Bangladesh, Sri Lanka, Pakistan, Taiwan, China and among other Asiatics, with a reported prevalence ranging up to 0.4% in Indian rural population (Murti et al., 1995). Epidemiological and in vitro experimental studies have shown that chewing areca nut (Areca catechu) is the major aetiological factor for OSF (Caniff and Harvey, 1981). Although there are regional variations in the type of areca nut products used in India, the betel quid (BQ) was the most popular and prevalent habit in ancient Indian culture. But in 1980, both areca quid products such as Pan masala (Areca quid) and Guthka (AQ tobacco) were introduced in Indian market as commercial preparations. Since then there has been an

increase in the use Pan Masala (Areca quid) and Guthka (AQ + T) in the younger age groups, which had lead to increased incidence of OSF (Gupta et al., 1998). Pan Masala (Areca quid) includes areca nut, catechu, lime, flavours and spices. Our previous hospital-based case-control study has proved strong association of Pan Masala (AQ) with highest relative risk (489.1) of development of OSF (Hazare et al. 1998). Guthka (AQ + T) contains all ingredients of Pan Masala (AQ) plus tobacco and other contents, that are closely guarded secretes and is a commercial substitute to local preparation popularly known as Kharra/Mawa (Sinor et al., 1990). The rapidly increasing prevalence of this habit can be judged from the reports that the Indian market for Pan masala (AQ) and Guthka (AQ + T) is worth 25 billion (US\$ 500 million) (Gupta and Ray, 2004). When the disease was first described it was classified as an idiopathic disorder (Schwartz, 1952).

Mortality/morbidity

OSMF has a high rate of morbidity because it causes a progressive inability to open the mouth, resulting in eating and consequent nutritional deficiencies. OSMF also has a significant mor-

- Progressive inability to open the mouth (trismus) due to oral fibrosis and scarring
- Oral pain and a burning sensation upon consumption of spicy foodstuffs
- Increased salivation
- Change of gustatory sensation
- Hearing loss due to stenosis of the eustachian tubes
- Dryness of the mouth
- Nasal tonality to the voice
- Dysphagia to solids (if the esophagus is involved)
- Impaired mouth movements (eg, eating, whistling, blowing, sucking)
- Laboratory findings:
 - Decreased hemoglobin levels
 - Decreased iron levels
 - Decreased protein levels
 - Increased erythrocyte sedimentation rate
 - Decreased vitamin B complex levels

tality rate because of it can transform into oral cancer, particularly squamous cell carcinoma, at a rate of 7.6%. Signs and symptoms of OSF are mentioned in Table 1.

Pathogenesis

The role of the constituents of areca nut in the pathogenesis of OSF has been studied in detail over last two decades. It is apparent that fibrosis and hyalinization of subepithelial tissues account for most of the clinical features encountered in this condition. Moreover, substantial amount of research on elucidating the etiology and pathogenesis appear to have been focused on changes in the extracellular matrix (ECM). It is logical to hypothesize that the increased collagen synthesis or reduced collagen degradation as possible mechanisms in the development of the disease. There are numerous biological pathways involved in the above processes and, it is likely that the normal regulatory mechanisms are either down regulated or up regulated at different stages of the disease (Figure 1 and Figure 2).

Quid has been defined as a substance or mixture of substances placed in the mouth or chewed and remaining in contact with the mucosa usually containing one or both of the two basic ingredi-

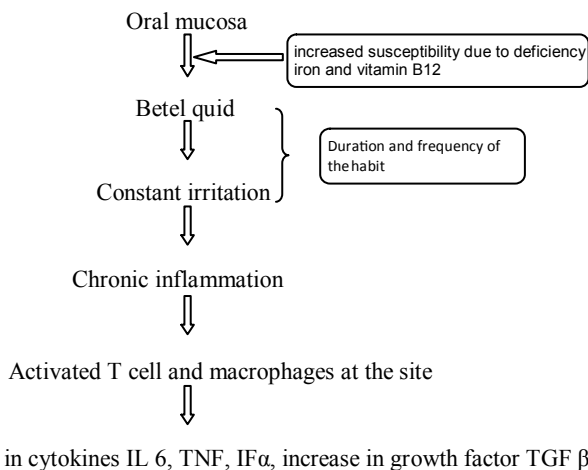

Figure 1: Initial events of the disease process oral mucosa which is in direct contact with the betel quid due to the habit, is the site of constant irritation (Rajalalitha and Vali, 2005).

Figure 2: Overall effect of activated TGF beta pathway. There is an increase in collagen production and cross linking (insoluble form) along with the decrease in the collagen degradation. This produces increased collagen deposition in the subepithelial connective tissue layer of the oral mucosa leading to OSF

ents tobacco and/or areca nut in raw or any manufactured or processed form (Zain et al., 1999). The major areca nut alkaloids are arecoline, arecadine, arecolidine, guayacoline and guacine (IARC anonymous, 1985). The important flavonoid components in areca nut are tannins and catechins. These alkaloids undergo nitrosation and give rise to N-nitrosamine which might have cytotoxic effect on cells (Hoffmann et al., 1994).

The betel quid is placed in the buccal vestibule for about 15 minutes to an hour and repeated 5 to 6 times a day which leads to constant contact between the mixture and oral mucosa. The alkaloids from the quid are absorbed into the mucosa and undergo metabolism. Microtrauma produced by the friction of coarse fibers of areca nut also facilitates diffusion of the alkaloids into the subepithelial connective tissue resulting in juxtaepithelial inflammatory cell infiltration (Chiang et al., 2002).

Oral submucous fibrosis (OSF) is widely considered to be a potent precancerous condition whose predominant characteristics are the excessive and abnormal deposition of extracellular matrix (ECM) components that may affect adversely the routine oral functions. From a clinico-pathologic point of view, fibrosis may be considered as a somewhat irreversible state of tissue alteration, during which resolution of the healing process fails to occur. Increasingly, it has become appreciated that certain of these actions of ECM derive from its ability to sequester and modulate the activity of specific growth factors (Nathan and Sporn, 1991). Of all of the growth factors, none has been found to have the diversity of effects on ECM ascribed to transforming growth factor-β (TGF-β). This peptide plays a critical role not only in synthesis and degradation of ECM but also in response of cells to ECM mediated through integrin receptors; moreover, specific components of the ECM, in turn, can both deliver TGF-β and regulate its activity (Roberts et al., 1988; Roberts et al., 1990).

The molecular events in the pathogenesis of OSF discussed by a 29. Rajalalitha and Vali, (2005): collagen production pathway and collagen degradation as regulated by TGF β and the flavonoids present in areca nut.

Collagen production pathway

There are three main events in this pathway activation of procollagen, elevation of procollagen proteinase levels, and up-regulation of lysyl oxidase (LOX activity).

Collagen is the most abundant protein in the human body and plays an important role in the structural element of connective tissue. They are triple helix stabilized by unusual crosslink. The processing of fibrillar collagen occurs in a stepwise manner. Procollagen genes are transcribed and translated to form procollagen monomeric chains. The genes COL1A2, COL3A1, COL6A1, COL6A3, COL7A1 have been identified as definitive TGF-β targets (Rajalalitha and Vali, 2005). The activation of collagen I and VII collagen gene expression by TGF-β has been demonstrated. The activation of procollagen genes by TGF-β is causing an increased expression of procollagen genes and hence increases collagen level in OSF. Elevation of procollagen proteinases such as PCP that cleaves C-terminal and PNP's (PNP1 and PNP 2) cleaves N terminal play essential role in pathogenesis of OSF. Thus, TGF-b may play an important role in inducing fibrotic tissue formation, while connective tissue growth fac-

tor (CTGF) is important in maintaining fibrosis. In the study conducted by Yi-Ting et al., (2009) found arecoline stimulated CTGF production in buccal mucosal fibroblasts (BMF). BMFs could contribute to the pathogenesis of OSF by producing CTGF during arecanut chewing. OSF could be driven by a wave of increased CTGF synthesis during arecanut chewing, accompanied by an increased local TGF- β concentration due to inflammation regularly found in OSF. Recent study has shown that curcumin (1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione), the major yellow pigment in turmeric, curry and mustard, has high antioxidant and anti-inflammatory activity and is widely used as a flavoring and coloring agent in foods and as an herbal medicine to treat chronic inflammatory diseases (Goel et al., 2008) suppresses the expression of extracellular matrix genes in activated hepatic stellate cells by inhibiting CTGF gene expression through suppressing ERK and NF- κ B signalling. Interestingly, researchers found curcumin could completely inhibit arecoline-induced CTGF synthesis and the inhibition is dose-dependent (Chen and Zheng, 2008).

Up-regulation of LOX

The copper content of areca nut is high and the levels of soluble copper in saliva may rise in volunteers who chew arecaquid (Trivedy et al., 1997). The same group showed that the oral mucosa of areca nut chewers had significantly raised levels of copper when compared with the control subjects (Trivedy et al., 2000). The association between copper and OSF has been linked on the basis that excess copper is found in tissues of other fibrotic disorders— Wilson's disease, Indian childhood cirrhosis and primary biliary cirrhosis. The enzyme lysyl oxidase is found to be upregulated in OSF (Trivedy et al., 1999). This is a copper dependent enzyme (Kagen and Trackenman, 1991) and plays a key role in collagen synthesis and its cross linkage. The possible role of copper as a mediator of fibrosis is supported by the demonstration of up regulation of this enzyme in OSF biopsies (Trivedy et al., 1999) and in OSF fibroblasts compared to normal fibroblasts grown in culture (Ma et al., 1995). Copper added at various concentrations in vitro has also been shown to increase proliferation of fibroblasts in culture (Trivedy et al., 2001). The fibroblasts in OSF have not only increased lysyl oxidase activities but also specific growth characteristics. This was evident with the reported cell doubling time of 3.2 days for OSF and 3.6 days for normal fibroblasts (Ma et al., 1995). Further, OSF fibroblasts grew more rapidly than normal as the former became confluent in 5 days compared to 6 days for the latter. However, another study based on ultrasound investigations of visceral organs in OSF patients reported that there was no evidence of fibrotic changes elsewhere. Faecal copper was also normal suggesting that the copper levels were within the tolerance levels (Rajendran et al., 2003). As the oral mucosa is directly exposed to the copper challenge in chewers its effect may well be local. These different growth characteristics may either be due to the direct effects of ingredients of areca nut or secondary to inflammatory factors mediated by areca nut such as IL-1, TGF- β , IGF, EG (Haque et al., 2000). The LOX activity is important of insoluble collagen due to cross linking. The process of cross linking gives tensile strength and mechanical properties to the fibers as well as makes the collagen fibers resistant to proteolysis tilting the balance towards a fibrotic condition as present in OSF.

Collagen degradation pathway

There are two main events modulated by TGF which decreases the collagen degradation, activation of inhibitor of matrix metalloproteinase gene TIMPs and activation of plasminogen activator inhibitor PAI gene.

Upregulation of cyclo-oxygenase

(COX-2)

It is known that OSF is associated with inflammatory changes in at least some stages of the disease. Prostaglandin is one of the main inflammatory mediators and its production is controlled by various enzymes such as cyclo-oxygenase (COX). Biopsies from buccal mucosa of OSF cases and from controls were stained for COX-2 by immune histochemistry and revealed that there was increased expression of the enzyme in moderate fibrosis and this disappeared in advanced fibrosis. This finding is compatible with the histology of the disease as there is lack of inflammation in the advanced disease. The above finding was confirmed by treating buccal mucosal fibroblasts with 80 μ g/ml arecoline in culture and revealed that COX-2 expression was up-regulated as early as half an hour, indicating this to be an early cellular response to arecoline at transcriptional level. COX-2 expression started to decrease when the arecoline concentration was increased upto 160 μ g/ml, and this may be due to cytotoxicity. Similar data have been reported in another study quoting 1.4–3.4-fold increase of PGE₂ production and 1.1– 1.7-fold increase of PGE_{1 α} when gingival keratinocytes were exposed to areca nut extracts (Jeng et al., 2000).

Oral submucous fibrosis is a prototype of pathological fibrosis sharing characteristics in common with other organ involvements where deposition of collagen is taking place primarily in the oral submucosa (Shiau and Kwan, 1979). It has been found that alkaloid (areca-nut) exposure of buccal mucosal fibroblasts may result in the accumulation of collagen (Harvey et al., 1986). A reduced degradation of the alpha 1(1) collagen trimer synthesized by OSF fibroblasts may induce the alteration of the ratio of alpha 1(1) : alpha 2 (1) chains (Kuo et al., 1995). Collagenase activity has been found to be reduced in OSF than in normal oral mucosa (Shieh and Yang, 1992). This evidence implies that OSF may be considered a collagen-metabolic disorder resulting from alkaloid exposure and individual variation in collagen metabolism.

Role of Heat shock proteins (HSP) in pathogenesis of OSF

HSP47, is a 47 kDa collagen-binding heat shock protein (HSP), which belongs to the serine protease inhibitor (serpin) superfamily containing a serpin signature sequence (17). HSP47 is known as a molecular chaperone that is specifically involved in the processing and quality control of collagen molecules Shung et al., (2008) first found that arecoline is capable of stimulating HSP47 mRNA expression in human BMFs. HSP47 plays an important role in the synthesis, processing, and assembly of various collagens. Previously, their data have shown that arecoline could enhance collagen synthesis in human gingival fibroblasts (Chang et al., 1999). Consistently, study by Shung Fa, found that HSP47 mRNA was upregulated by arecoline in human BMFs. Thus, authors propose that the accumulation of collagen in oral mucosal connective tissue may be caused by a simultaneous effect on HSP47 by areca quid chewing.

Role of basic fibroblastic growth factor (bFGF) in pathogenesis of OSF

The FGFs, which often interacts synergistically with other growth factors, may possibly have an effect on extracellular matrix (ECM) deposition. The biological activity of basic fibroblast growth factor (bFGF) in fibroblast, the surrounding matrix and its role as a mediator in the pathogenic process of OSF is of paramount importance, as a better understanding of the cytokines and cytokine networks involved in the early stages of fibrosis could widen newer therapeutic strategies and better the treatment options for OSF.

The bFGF may either directly stimulate endothelial cell proliferation or facilitate VEGF-endothelial cell interaction through the modulation of endothelial cell integrin or VEGF-receptor expression (Salcedo et al., 1999). The increased bFGF expressivity in endothelial cells along with fibroblasts in OSF cases was an important observation, as bFGF potentiates leukocyte recruitment to inflammation by enhancing endothelial adhesion molecule expression (Zittermann and Issekutz, 2006). It has also been demonstrated that endothelial cell derived IL-1 and bFGF modulate fibroblast properties independently, which supports the hypothesis that altered endothelial cell-fibroblast communication may be involved in the pathogenesis of fibrosis (Wojas-Pelc and Lipko-Godlowska, 2005). The endothelial cell and fibroblast dysfunction may be linked through the paracrine activity of soluble endothelial cell products (Denton et al., 1997). Mast cells which are found in the early stages of OSF are indicated to be a primary source of heparin and may serve as a significant source for heparin binding growth factor, the bFGF, in disease processes (Qu et al., 1995). The altered stromal distribution of bFGF in OSF could be because of lower stromal cell concentration and aberrant extracellular deposition of cytokine (Yoon et al., 2001). Another possible explanation for the observed abnormality in OSF may be because of a defect in either ligand production or cell surface deposition of the cytokine. Therefore, a potential defect in the extracellular binding of bFGF might involve a different set of bFGF binding molecules including heparin-like glycosaminoglycans.

Recently, the direct effect of (basic fibroblasts growth factor) bFGF-1 and TGF- β , on fibroblast proliferation and collagen synthesis using cultured oral fibroblasts have shown opposing effects on growth, differentiation and extracellular matrix accumulation. While bFGF was autorepressive and catabolic, TGF- β has shown to be autoinductive and anabolic, thus representing a part of feedback mechanism controlling stromal growth. However, when bFGF and TGF β , were associated, the anabolic effects prevailed (Silverio-Ruiz et al., 2007). Contrary to this effect, bFGF was found to be the most potent growth factor in increasing proliferation, glycosaminoglycans synthesis and promoting collagen synthesis in TMJ disk cells (Detamore and Athanasiou, 2004). Additional studies to test the effect of bFGF and TGF- β alone and in combination on cultured fibroblasts from OSF tissues may prove beneficial, as these studies may provide a greater insight into its pathogenesis and offer novel options for therapeutic intervention.

Precancerous nature and malignant transformation

The precancerous nature of OSF was first described by Paymaster in 1956 when he observed slow growing squamous cell

carcinoma (SCC) in one third of the patients with the disease (Paymaster, 1956). This was confirmed by various groups and Pindborg in 1972 put forward five criteria to prove that the disease is precancerous (Pindborg et al., 1984). They included, high occurrence of OSF in oral cancer patients, higher incidence of SCC in patients with OSF, histological diagnosis of cancer without any clinical suspicion in OSF, high frequency of epithelial dysplasia and higher prevalence of leukoplakia among OSF cases (Pindborg et al., 1967). Malignant transformation rate of OSF was found to be in the range of 7–13%. According to long term follow-up studies a transformation rate of 7.6% over a period of 17 years was reported (Murti et al., 1985). Authors hypothesize that dense fibrosis and less vascularity of the corium, in the presence of an altered cytokine activity creates a unique environment for carcinogens from both tobacco and areca nut to act on the epithelium. It could be assumed that carcinogens from areca nut accumulate over a long period of time either on or immediately below the epithelium allowing the carcinogens to act for a longer duration before it diffuses into deeper tissues. Less vascularity may deny the quick absorption of carcinogens into the systemic circulation (Tilakaratne et al., 2006). An observation which is still intriguing in the pathogenesis of OSF and its subsequent malignant transformation is the often reported cases of carcinomas, rather than sarcomas associated with the disease. To the best of our knowledge no case of sarcomatous transformation had been reported of this disease, even though it is of stromal origin. The concept of a link between stromal cell maturation and adjacent epithelial proliferation was introduced more than 20 years ago (Cunha et al., 1980) and has gained support since. This interaction is mediated by soluble paracrine signals and ECM components secreted from developing mesenchyme that induce the adjacent epithelia to proliferate rapidly. A new balance of mesenchymal-epithelial crosslink is reached during tissue maturation (Bhowmick et al., 2004). During tumorigenesis, however, the prevailing model suggests a process whereby pre-cancerous epithelial cells acquire multiple genetic mutations and the associated stroma becomes “activated” commonly expressing myofibroblastic markers (Ronnov-Jessen et al., 1996). The characteristics of an activated carcinoma-associated fibroblast are not completely understood. Such cells are presumed to express α smooth muscle actin, ECM proteins, and growth factors that act in an autocrine and paracrine fashion to potentiate and support the survival of a tumor (Bhowmick et al., 2004).

Treatment

The list of other treatment modalities (Table 2) is extensive and includes use of micronutrients and minerals, carbon dioxide laser, pentoxifylline, lycopene, interferon gamma, turmeric, hyalase, chymotrypsin and collagenase. As fibrosis cannot be reversed, when mouth opening is severely limited surgical interventions, such as myotomy, coronoidectomy and excision of fibrotic bands, are required. Reconstruction using such techniques as buccal pad flap, superficial temporal flap and forearm flap, can also be performed. Alternative procedures, such as insertion of an oral stent, physiotherapy, local heat therapy, mouth exercises using acrylic carrots and ice cream sticks, have been tried with variable rates of success. In most cases, depending on the stage of disease and extent of oral involvement, therapy consisting of a combination of the above-mentioned drugs and surgery might be useful.

Treatment	Treatment Details
Micronutrients and minerals	Vitamin A, B complex, C, D and E, iron, copper, calcium, zinc, magnesium, selenium and others
Lycopene	6 8 mg twice a day for 2 months
Pentoxifylline	400 mg 3 times a day for 7 months
Interferon gamma	Intralesional injection of interferon gamma (0.01–10.0 U/mL) 3 times a day for 6 months
Steroids	Submucosal injections twice a week in multiple sites for 3 months
Steroids	Topical for 3 months
Hyalase + dexamethasone	-
Placental extracts	Turmeric ³⁰ Alcoholic extracts of turmeric (3 g), turmeric oil (600 mg), turmeric oleoresin (600 mg) daily for 3 months
Chymotripsin, hyaluronidase and dexamethasone ³¹	Chymotripsin (5000 IU), hyaluronidase (1500 IU) and dexamethasone (4 mg), twice weekly submucosal injections for 10 weeks

Table 2: Treatment modality for OSF (Auluck et al., 2008).

Conclusion

In summary, the available literature indicates that the main aetiological factors for OSF are the constituents of areca nut, mainly arecoline, whilst tannin may have a synergistic role. These chemicals appear to interfere with the molecular processes of deposition and/or degradation of extracellular matrix molecules such as collagen, causing imbalance in the normal process. The most likely events that take place with regards to the above imbalance may be reduced phagocytosis of collagen by fibroblasts, up or down regulation of key enzymes such as lysyl oxidase, matrix metalloproteinases and tissue inhibitors of matrix metalloproteinases. The process may also be influenced by increased secretion of inflammatory cytokines, growth factors and decreased production of anti-fibrotic cytokines. Although the above mechanisms may explain the induction, maintenance and progression of fibrosis in OSF, further research is required in order to identify the mechanism leading to carcinogenesis in this fibrotic oral mucosa. Nutritional deficiencies may not play a primary role but it could synergies the symptomatology by contributing to epithelial atrophy. Although the involvement of HLA and genetic predisposition has been reported, specific haplotypes have not been determined. The individual mechanisms operating at various stages of the disease—initial, intermediate and advanced—need further study in order to propose appropriate therapeutic interventions.
