1. Introduction

Intravesical Bacillus Calmette-Guérin (BCG) immunotherapy is considered useful for some patients with primary superficial bladder carcinoma [1]. However, 60% of patients undergoing this therapy develop several side effects such as pneumonitis, sepsis, multiple organ failure, and severe granulomatous inflammation [2–4]. Reiter’s syndrome (reactive arthritis) is one of the major side effects caused by urinary tract infection (UTI) triggered by BCG. Reactive arthritis is considered to be derived from infection by microorganisms via membranes of the digestive, urogenital, or respiratory systems, although microorganisms themselves are not found at sites of arthritis [2]. This is the first report of Reiter’s syndrome with reactive temporomandibular arthritis caused by BCG immunotherapy.

2. Case report

A 48-year-old male underwent transurethral resection of a bladder tumor under a diagnosis of bladder carcinoma in the Department of Urology at the University of Tokyo Hospital on August 17, 2004. After bladder carcinoma resection, a total of eight intravesical BCG immunotherapy treatments using an immunobladder were planned and started from September 10. However, after the fifth treatment, the patient developed a fever and reactive arthritis on October 14, and so the treatment was discontinued. The symptoms included trismus, whereby he could not even put one finger into his mouth, eating disorder, limited ambulation due to painful swelling of the bilateral knee joints, a fever of 39 °C, blepharedema, and blepharoconjunctivitis. The patient was diagnosed with Reiter’s syndrome since he had the triad of arthritis, urethritis, and conjunctivitis. These symptoms gradually deteriorated. Sharp pain of the bilateral temporomandibular area was more marked than at any other joint. The laboratory data on October 18 are shown in Tables 1 and 2. These results indicated possible tuberculosis infection. He was then administered rifampicin at 450 mg and isoniazid at 200 mg per day, and the anti-inflammatory drug diclofenac sodium (voltaren®) several days after. By the end of October, he gradually became able to walk with physiotherapy. The swelling of the knee joints fully resolved by January 2005, and he could walk normally. The mouth-opening distance increased, although the sharp pain of the left temporomandibular joint persisted. The laboratory data on January 7, 2005, are shown in Tables 1 and 2. The antiphthisics were discontinued on January 20. HLA antigen presence, one of the potent indices of Reiter’s syndrome, was investigated on November 5, 2004. No positive indices [HLA-A31(19), HLA-B61(40), B48, or HLA-B27] were detected. Urinalysis for the acid fast bacillus on November 5, 2004, and January 7, 2005, revealed negative results.

The severe pain of the temporomandibular joint persisted and, therefore, the attending urologist referred him to our maxillofacial surgery department on April 1, 2005. It had been 5 months
The more he exercised, the more smoothly he was able to move his jaw. (iii) To do three sets of these exercises daily. (i) To position the mandible slowly to the left and right sides, and then forwards and backwards 10 times, respectively. (ii) To open the mouth as wide as possible 10 times, with the fingers in the mouth. (iii) To do three sets of these exercises daily according to instructions given in written form. He continued the exercise for 3 months without medication, and the pain reduced. The more he exercised, the more smoothly he was able to move and open his mouth. He became able to open his mouth without inconvenience after 7 months of this treatment. Panoramic radiography showed no change of the temporomandibular joint after 1 year of this therapy (Fig. 1B). At present, he can open his mouth to a distance of 48 mm with neither pain nor difficulty.

3. Discussion

We have reported a case of Reiter’s syndrome with reactive temporomandibular arthritis caused by BCG immunotherapy. Many investigations have reported Reiter’s syndrome [5–11]. There are a few reports concerning Reiter’s syndrome (reactive arthritis) caused by intravesical BCG immunotherapy [1–3]. However, these did not comment on temporomandibular arthritis. Reviewing the literature, this is the first report of Reiter’s syndrome of the temporomandibular joint following intravesical BCG immunotherapy. Furthermore, this case is rare because the temporomandibular area pain was severe and lasted for a prolonged period.

Intravesical Bacillus Calmette-Guérin (BCG) immunotherapy is useful for antitumor therapy for some patients with primary superficial bladder carcinoma, or, particularly, superficial carcinoma. However, for intravesical BCG immunotherapy [1–3], there have been many reports of side effects such as pneumonitis, sepsis, multiple organ failure, and severe granulomatous inflammation. Nevertheless, after urinary tract infection (UTI) of BCG [2], dermatitis and blepharoconjunctivitis occur secondarily. HLA-B27, one of the indices of Reiter’s syndrome, was negative in this case. However, a diagnosis of Reiter’s syndrome is more likely, because about 44% of patients with Reiter’s syndrome are HLA-B27-negative [2,12].

Lyme disease [13] is another candidate. Lyme disease is caused by *Ixodes dammini* or related ixodid ticks showing regional specificity. Arthritis develops in many patients at stage 3, which is several weeks to years later from tick biting. Lyme disease is associated with DR2. We cannot deny the possibility of Lyme disease, because DR2 and IgG antibody against the Lyme spirochete were not investigated. However, Reiter’s syndrome seems more appropriate for this case. The first reason is that the patient showed no clinical history of symptoms of stage 1 Lyme disease, characterized by skin lesions erythema chronicum migrans, accompanied by meningitis and blepharoconjunctivitis occur secondarily. HLA-B27, one of the indices of Reiter’s syndrome, was negative in this case. However, a diagnosis of Reiter’s syndrome is more likely, because about 44% of patients with Reiter’s syndrome are HLA-B27-negative [2,12].

Lyme disease [13] is another candidate. Lyme disease is caused by *Ixodes dammini* or related ixodid ticks showing regional specificity. Arthritis develops in many patients at stage 3, which is several weeks to years later from tick biting. Lyme disease is associated with DR2. We cannot deny the possibility of Lyme disease, because DR2 and IgG antibody against the Lyme spirochete were not investigated. However, Reiter’s syndrome seems more appropriate for this case. The first reason is that the patient showed no clinical history of symptoms of stage 1 Lyme disease, characterized by skin lesions erythema chronicum migrans, accompanied by meningitis or flu-like symptoms. The second reason is that he had a history of intravesical BCG immunotherapy treatments which may cause Reiter’s syndrome.

Considering the fact that the present patient showed the triad of arthritis, urethritis, and conjunctivitis, he was diagnosed with Reiter’s syndrome. The pain of the temporomandibular area persisted for a prolonged period. Sharp pain of the temporomandibular area was more marked than that of other areas such as the knee joints. The inflammatory level might have been higher in the temporomandibular area than in the other joints at the time he developed this disease. The patient seemed to have recovered from the primary stage of acute inflammation on the first visit to our department, although the pain of the temporomandibular area still persisted. The reason why only the left temporomandibular pain persisted with less pain in the right temporomandibular joint was unclear. The irregular contour of the left condylar cortical bone may affect this pain. Mouth-opening exercise with the use of...
Fig. 2. Magnetic resonance imaging (MRI, proton density images) at the first examination. Left TMJ MR image at mouth opening reveals effusions of both upper and lower compartments and a low signal density area on the top of the condyle that is also depicted on the mouth closing position image with a diffused irregular contour of the condylar cortical bone. (A) Sagittal figure of the left temporomandibular joint in a closed state. (B) Sagittal figure of the right temporomandibular joint in a closed state. (C) Sagittal figure of the left temporomandibular joint in an open state. (D) Sagittal figure of the right temporomandibular joint in an open state.

anti-inflammatory drugs relieved the pain of the temporomandibular joint. These results suggest that controlled rehabilitation is effective to recover the function of the temporomandibular joint.
